	Urgent	**Not Urgent**
Important	**DO** ● Fetch and format historical daily stock prices (Open, High, Low, Close,Volume) for HYBE, JYP, and YG Entertainment. ● Compute daily percentage returns (so that I can compare all agencies on an equal percentage scale) and rolling 20-day standard deviation (volatility) for each agency (this would let me see the unusualness of a stock dropping; if it dropped 2-3%, but the stock moves 2-3% a day anyway, this would not be an unusual change). ● Write a function to extract stock performance in a 30-day window (±15 days) around landmark comeback dates (for example: BTS's March 2026 comeback, BLACKPINK's comeback, or TWICE's comeback). ● Generate clear matplotlib line charts displaying price movement and abnormal returns around the targeted comeback dates compared to baseline trends.	**SCHEDULE** ● Check if entertainment agencies usually move up and down together as a group. Then, see what happens when one big group (like BTS) has a huge comeback or a major controversy; does it make that company's stock break away from the others, and does it eventually snap back to match the industry trend? ● Measure how wild a company's stock behavior gets during a specific group's milestones (like a BTS, BLACKPINK, or TWICE release) compared to regular boring business financial reports. This would show whether an agency's stock is dependent on just one single music group. ● Track how fast a new music video gets views in its first week on YouTube. Then, check if that internet hype actually connects to the stock price jumping up over the next 48 hours.
Not important	**DELEGATE** ● Delegate raw price extraction and exchange rate handling to the yfinance library. ● Delegate daily return percentage changes, rolling window averages, and standard deviation calculations to pandas and numpy rather than writing manual Python loops. ● Delegate figure layout, axis scaling, and PNG rendering to matplotlib.pyplot.	**DELETE** ● Building an active trading execution system that executes live market orders on South Korean exchanges based on social media sentiment. ● Fine-tuning a ML model to parse Korean-language fan forums or Twitter posts for sentiment scoring. ● Building a full-stack React, Streamlit, or mobile application interface to display stock charts instead of using standard Jupyter Notebook outputs.
